

Abstract

The invention relates to a device for introducing forces into a luggage compartment (1) and for transferring and/or distributing the forces and/or stresses in vehicles, particularly in fast-traveling vehicles such as aircraft, ground vehicles and watercraft, e.g. express trains, speedboats and the like. In order to create a device of this type, which has the most simple possible design and can be economically produced, the invention provides that the introduction of forces into the luggage compartment ensues via a ceiling-side connecting element, for example, provided in the form of a strip (8) that distributes forces or stresses.
